

Figure 1. Analysis framework for ecological composition and longitudinal OU dynamics

A

Harmonized single-cell ecological representation

113 regenerated participants → 104 compositionally eligible
TNK + B + Myeloid renormalized to sum to 1

B

Ecological structure, stability, and compositional sensitivity

Raw-versus-CLR ARI tests representation sensitivity.
Contexts are descriptive coarse-graining, not fixed leukemia ecotypes.

C

Corrected longitudinal x endpoint and model-input construction

Final primary cohort: 34 participants | 241 x observations
| 207 positive-time transitions
Irregular sampling retained explicitly for the OU transition likelihood

D

OU inference, participant-level validation, and robustness

Primary question: does continuous ecological composition add longitudinal information beyond coarse ecological-context labels?
